# Brightness

Assumption

- No absorption, emission, scattering or any other propagation effect along the path, or propagation through empty space
- Geometric optics

Brightness - $B(\theta, \phi, \nu, t)$

- Units - $W\ m^{-2}\ sr^{-1}\ Hz^{-1}$
- AKA Surface Brightness, Specific Intensity or Spectral Radiance
- Conserved along a ray in empty space

# Power received at a detector

$$dW = B(\theta, \phi, \nu) \;\; cos\theta dA \;\; d\Omega \;\; d\nu$$

$dW$ - W
$B(\theta, \phi) - W \; m^{-2} \; sr^{-1} \; Hz^{-1}$

Practical quantitative definition

$$B(\theta, \phi, \nu) = \frac{dW}{d\Omega \; cos\theta dA \;\; d\nu}$$

- Intrinsic property of the source
- Independent of the distance from the source (ONLY for a resolved object)
- Can be thought of as energy *received* at the detector OR as energy *emitted* by the source.

# Total Intensity

Total Intensity - Specific Intensity integrated over frequency

Conservation of Brightness applies here as well

Example: Looking through a telescope

# Flux Density, $S_\nu$

- Total spectral power received from a source by a detector of unit area.
- $S_\nu = \int_{Source} B(\theta, \phi, \nu)\ cos\theta\ d\Omega$
- For a source with a well defined solid angle
- Unit - $W\ m^{-2}\ Hz^{-1}$
- 1 $Jansky\ (Jy) = 10^{-26}\ W\ m^{-2}\ Hz^{-1}$

# Flux Density, $S_\nu$

- Not an intrinsic property of the source - dependent on the distance to the source
- The $cos\theta$ is $\sim$1.0 if angular size $<<$ 1 rad
- Useful for compact (unresolved) sources

# Luminosity

Spectral Luminosity

- Total power radiated by the source per unit bandwidth at $\nu$
- $L_\nu = 4\pi\ d^2\ S_\nu$
- Property of the source
- Involves $d$, the distance to the source!

Bolometric Luminosity

- Total power radiated by the source integrated over the entire spectrum
- $L_{bol} = \int_0^\infty L_\nu\ d\nu$

# A Quick Application

Assume the Sun to be blackbody at 5800 K. What is the specific intensity of the Sun at $\nu = 10 GHz$? What is the flux density of the Sun measured at Earth

1. Verify if Rayleigh Jeans law is applicable
2. Use it to compute $B_\nu$
3. To get $S_\nu$, compute the angular size of the Sun. Assume the Sun to be a disc of uniform *Brightness* and integrate over it.

How will $B_\nu$ and $S_\nu$ change if they are measured from Mars, rather than the Earth?

Submit your solution in the next class!

# Gain of an Antenna, $G(\theta, \phi)$

$$G(\theta,\phi) = \frac{Power\ transmitted\ towards\ (\theta,\phi)\ (per\ unit\ solid\ angle)}{Power\ transmitted\ by\ an\ isotropic\ antenna\ (per\ unit\ solid\ angle)}$$

- Dimensionless
- Measure of how *directional* an antenna is
  - Gain of an isotropic antenna is 1.0
- Usually expressed in *dB*, i.e. $G(dB) = 10 \times log_{10} G$
- For a lossless antenna, same as the *Directivity* as well.

# Gain of an Antenna, $G(\theta, \phi)$

- Conservation of Energy (for a lossless antenna)

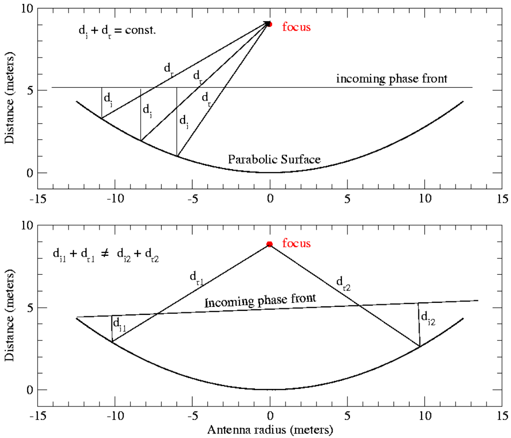
$$\implies < G > = \frac{\int_{sphere} G(\theta, \phi)\ d\Omega}{\int_{sphere} d\Omega} = 1$$

- $\int_{sphere} d\Omega = 4\pi$

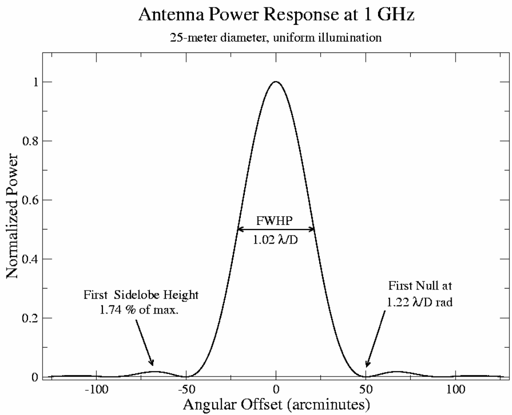
$$\implies \int_{sphere} G(\theta, \phi)\ d\Omega = 4\pi$$

- $\Delta\Omega \sim \frac{4\pi}{G_{max}}$

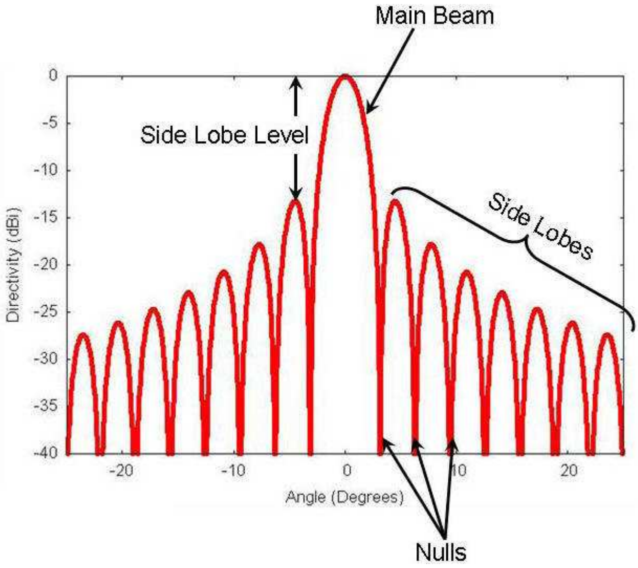
# Directivity of a Parabolic Dish



# Directivity of a Parabolic Dish



# Directivity of a Parabolic Dish



# A Measured Antenna Pattern (ATA)

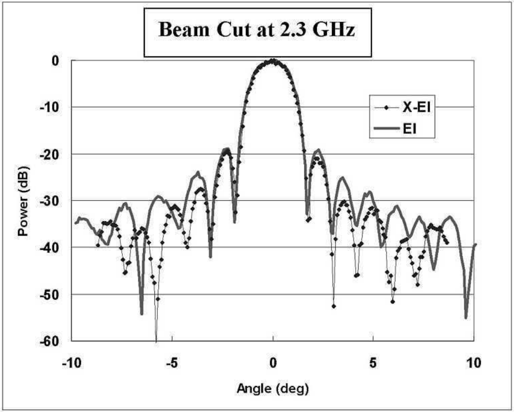


Figure 1: Two cuts through the primary beam pattern of one of the ATA dishes.

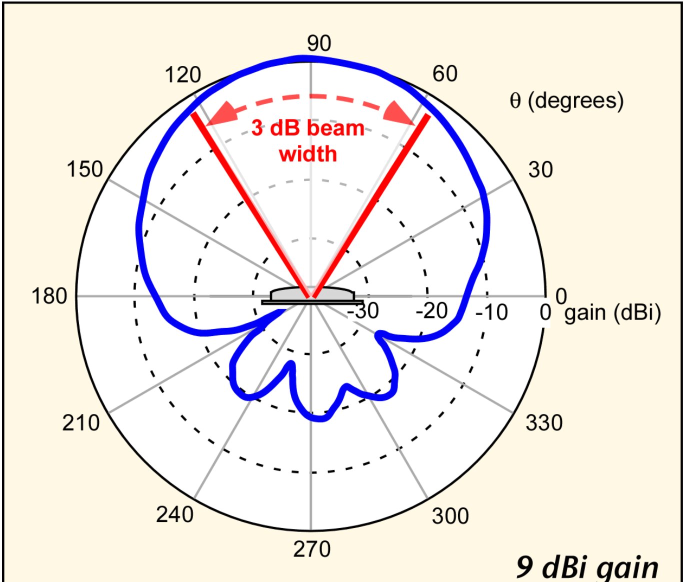
# Antenna Pattern of a Patch Antenna



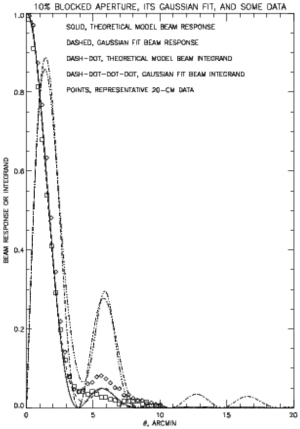


Fig. 4.— Normalized power pattern $P_n$, and also the integrand $\theta P_n$, for **(1)** the standard model of a uniformly illuminated 10% blocked aperture (solid, dash-dot lines), and **(2)** its Gaussian-fit counterpart (dash, dash-dot-dot-dot lines). The squares and diamonds are representative data points for $P_n$ from the LBW feed at 1415 MHz, obtained by averaging different cuts in one single observing pattern.

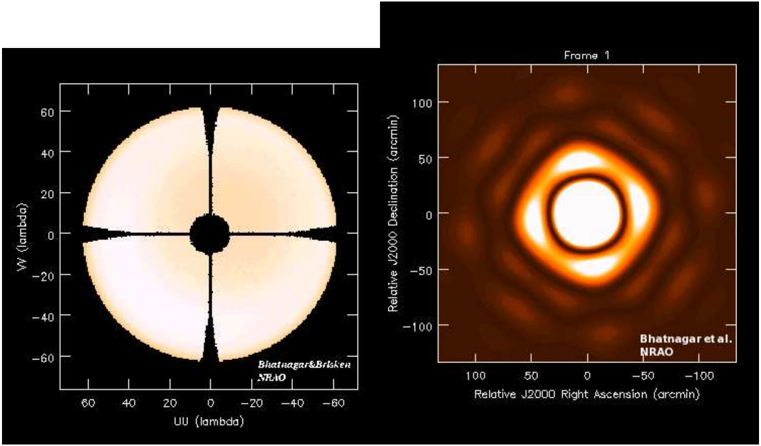
# A more sophisticated perspective

$E(\psi, \eta)$ - Aperture illumination (electric field distribution across the aperture)
$\psi$ and $\eta$ - aperture coordinates

$U(\alpha, \beta)$ - Far field electric field (diffraction pattern)
$\alpha$ and $\beta$ - directions relative to the optical axis of the telescope

$E(\psi, \eta)$ and $U(\alpha, \beta)$ form a Fourier transform pair

# An Example (Model for VLA 1420 MHz)



# Normalised Antenna Power Pattern, $P(\theta, \phi, \nu)$

$$P(\theta, \phi, \nu) = \frac{G(\theta, \phi, \nu)}{G(\theta_0, \phi_0, \nu)}$$

where $\theta_0$ and $\phi_0$ define the optical axis of the aperture.

- $$\int_{sphere} P(\theta, \phi, \nu)\, d\Omega = \Omega_A$$

  $\Omega_A$ – Beam solid angle

- $\lambda^2 = \Omega_A \times A_{eff}$
- For an isotropic antenna $A_{eff} = \frac{\lambda^2}{4\pi}$

# Gain and Aperture

$G = \frac{A_{eff}}{\lambda^2/4\pi}$, $A_{eff}$ – Effective collecting area

$A_{eff} = \eta \, A_{geom}$

- $\eta$ typically in the range 0.35 – 0.7
- GMRT: $\eta \sim$ 0.65–0.60 in the range 150 – 610 MHz, and $\sim$ 0.4 at 1400 MHz.
- J-VLA: $\eta$ peaks at 3 GHz at $\sim$0.62, and drops to $\sim$0.45 at 1.4 GHz and $\sim$0.34 at 45 GHz
- ALMA: $\eta \sim$ 0.75–0.45 in the range 35 – 850 GHz

# Spectral Power

$$W = \int_{\nu} \int_{aperture} \int_{\Omega} B(\theta, \phi, \nu) \;\; cos\theta dA \;\; d\Omega \;\; d\nu \quad W$$

$$w_{\nu} = \int_{aperture} \int_{\Omega} B(\theta, \phi, \nu) \;\; cos\theta dA \;\; d\Omega \quad W \; Hz^{-1}$$

$$w_{\nu} = A_{eff} \int_{\Omega} B(\theta, \phi, \nu) \;\; cos\theta \;\; d\Omega \quad W \; Hz^{-1}$$

$$w_{\nu} = A_{eff} \int_{\Omega} B(\theta, \phi, \nu) \;\; P(\theta, \phi, \nu) \;\; d\Omega \quad W \; Hz^{-1}$$

For a uniform source of Brightness $B_u$, this becomes
$w_{\nu} = \frac{1}{2} \; A_{eff} \; B_u \; \Omega_A \quad W \; Hz^{-1}$
