Galaxy formation and evolution in one diagram

see review by Kormendy & Kennicutt (2004)

Feedback and galaxy evolution

Credit: Phil Hopking

- 10⁸ year galaxy free fall timescale
- $10^7 10^8$ year lifetime of massive stars ı
- $10^7 10^8$ year active phase of AGN
- few times 10⁸ year rotation period of a galaxy
- 10⁹ year time required for two large galaxies to merge
- 10¹⁰ year lifetime of the galaxy

Typical time taken to cross a massive structure once. Indicates the time needed to reach equilibrium in the system. For a MW type galaxy it is $\sim 10^8$ yr. For a cluster, it is $2\times 10^9 {\rm yr}$. Young clusters have not yet reached equilibrium.

Galaxy merger

(c) Interaction/"Merger"

- now within one halo, galaxies interact & lose angular momentum
- SFR starts to increase
- stellar winds dominate feedback
- rarely excite QSOs (only special orbits)

(b) "Small Group"

- halo & disk grow, most stars formed - secular growth builds bars & pseudobulges - "Seyfert" fueling (AGN with Mo>-23)

- cannot redden to the red sequence

(d) Coalescence/(U)LIRG

- galaxies coalesce: violent relaxation in core - gas inflows to center:
- starburst & buried (X-ray) AGN - starburst dominates luminosity/feedback,
- but, total stellar mass formed is small

(e) "Blowout"

- BH grows rapidly: briefly dominates luminosity/feedback - remaining dust/gas expelled
- get reddened (but not Type II) QSO: recent/ongoing SF in host high Eddington ratios merger signatures still visible

(f) Quasar

- dust removed: now a "traditional" QSO - host morphology difficult to observe: tidal features fade rapidly
- characteristically blue/young spheroid

- QSO luminosity fades rapidly - tidal features visible only with very deep observations - remnant reddens rapidly (E+A/K+A) "hot halo" from feedback - sets up quasi-static cooling

- star formation terminated - large BH/spheroid - efficient feedback - halo grows to "large group" scales: mergers become inefficient - growth by "dry" mergers

two hour exam with 35% weightage open notes and bring a scientific calculator

- You will each have 20 minutes to speak with 5 minutes for questions.
- You will be graded on
 - Content (10 marks): Did you place the talk in context? Did you read and understand your paper and auxiliary papers? Did you answer the questions well?
 - Presentation (10 marks): Were the slides well ordered? Was text legible? Were figures readable? Did you pace the presentation well? Was your speech clear and confident?
 - Timeliness (5 marks): full marks for going -4 to +2 of specified time. Strong penalties outside this range.

A B b 4 B b

Galaxy formation - proto galaxy definition

- Galaxy in the first X % or Y yrs of its life (X=?, Y=?)
- Galaxy which has formed X % of its stars (X=?)
- Galaxy which has assembled X% of its final mass (X=?)
- Initial density fluctuation which has not formed any stars yet
- Galaxy at a very high redshift z > Z (Z=?)
- Generally we think of the progenitors of massive galaxies today, roughly in the first Gigayear of their life, i.e., at $z \gtrsim 5$
- We certainly expect vigorous star formation to be occuring, and therefore luminous objects

< ロ > < 同 > < 回 > < 回 >

Galaxies collapse and cool. The binding energy released is:

$$|E_{bind,gal}| \simeq 1.2 \times 10^{59} \mathrm{erg} \times (M_{cool}/10^{11} M_{\odot}) (V_{3D}/250 \mathrm{km s}^{-1})^2$$

where M_{cool} is the total mass that can cool radiatively.

$$|E_{\textit{bind},\star}| \simeq 4 imes 10^{58} \textit{erg} imes (M_{\Sigma\star}/10^{10} M_{\odot}) (\langle M
angle/M_{\odot}) (\langle R
angle/R_{\odot})^{-1}$$

 $M_{\Sigma\star}$ is the total mass converted to stars, $\langle M \rangle$ is the average star mass and $\langle R \rangle$ is the average star radius.

$E_{nuc} \simeq \epsilon M_{\Sigma\star} c^2 \Delta X \simeq 10^{60} \mathrm{erg}(\epsilon/0.001) (M_{\Sigma\star}/M_{\odot}) (\Delta X/0.05)$

Using an average bolometric luminosity $\langle L_{bol} \rangle$ and the average duration of the active episode Δt

 $E_{AGN} \sim \langle L_{bol} \rangle \Delta t \simeq 1.2 \times 10^{60} \mathrm{erg} (L_{bol}/10^{10} L_{\odot}) (\Delta t/10^8 \mathrm{yr})$

We expect a release of $\Delta E \sim 10^{60}$ ergs from a typical protoelliptical but over what time scale?

- $\bullet\,$ The starburst time scale of $\sim 10^7-10^8\,yrs$
- $\bullet\,$ The free-fall time scale of $\sim 10^8\,\, yrs$
- $\bullet\,$ The merging time scale of $\sim 10^9 \; \text{yrs}$

This gives $L_{PG} \sim 10^{11} - 10^{12}L_{\odot}$. Given the luminosity distances to $z \sim 6 - 8$, the expected apparent magnitudes are in the range ~ 26 to 30 mag. A few % of the total energy is in recombination lines, e.g., Ly α . Is there dust obscuration? No: use optical/near-IR, Yes: use submm-FIR surveys

SAURON (lenslets), SAMI, CALIFA (fibers), MUSE (mini-slits) There are now IFU (3D) spectrographs on most large optical telescopes of the world.

With SDSS V, the local volume mapper program will carry out IFU spectroscopy of the Milky way and nearby galaxies.

For multi-fiber spectroscopy, the DESI survey with its robotically positioned fibres will obtain spectra for about 40 million of galaxies.

SAURON - now decommisioned

LSST versus SDSS depth

Many new dwarf galaxies will be detected

*L*_{*} volume sampled by different surveys

Distant Red Sequence galaxies

• • • • • • • • • • • • •

Expected LSST areas of contribution to the study of galaxies

- Demographics of high redshift populations
- Demographics of LSB and dwarf galaxies
- Mergers, interactions and the environment
- Quantifying the biases and uncertainties
- Clusters and cluster galaxy evolution, intracluster light (intracluster novae)
- Observational confirmation of HOD
- many research projects could be done in citizen science mode.
