Galaxies: Structure, formation and evolution

Yogesh Wadadekar

Jan-Feb 2024

IUCAA-NCRA Grad School 1/43

$$rac{GM}{\langle R
angle} = k_E rac{\langle V
angle^2}{2}$$

the 3D velocity and radius will be some scaled version of the projected version. $R = k_R \langle R \rangle$, $V^2 = k_V \langle V \rangle^2$, $L = k_L I R^2$ Then one can write:

$$R = K_{SR} V^2 I^{-1} (M/L)^{-1}, L = K_{SL} V^4 I^{-1} (M/L)^{-2}$$

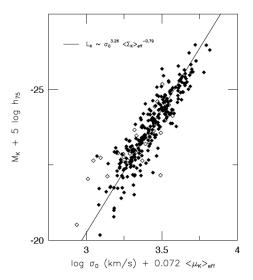

where the structure coeffients

$$K_{SR} = \frac{k_E}{2Gk_Rk_Lk_V}, K_{SL} = \frac{k_E^2}{4G^2k_R^2k_Lk_V^2}$$

• • • • • • • • •

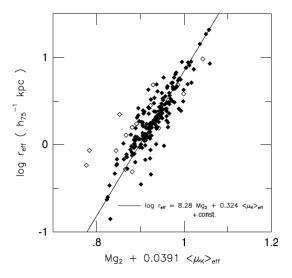

What do deviations of the observed relations from these scalings indicate?

Alternate FP - Luminosity instead of size

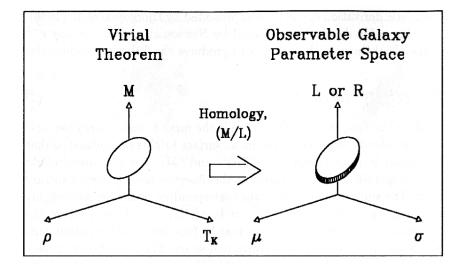

Star formation history connected to structural and dynamical properties

Alternate FP - Metallicity instead of σ

Chemical evolution connected to structural properties

Virial Theorem and the Fundamental Plane

If we assume homology and attribute all of the FP tilt to the changes in (M/L),

$$(M/L) \sim L^{lpha}, lpha \sim 0.2$$
 (vis)or ~ 0.1 (IR)

List two ways of changing M/L in a systematic way

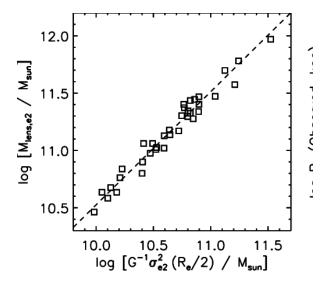

If we assume homology and attribute all of the FP tilt to the changes in (M/L),

$$(\textit{M}/\textit{L}) \sim \textit{L}^{lpha}, lpha \sim 0.2 (\textit{vis})\textit{or} \sim 0.1 (\textit{IR})$$

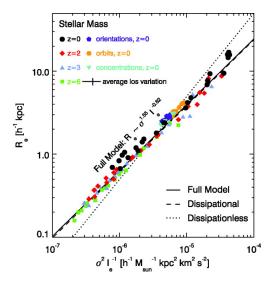

List two ways of changing M/L in a systematic way

- change the IMF
- 2 change $M_{\rm visible}/M_{\rm dark}$

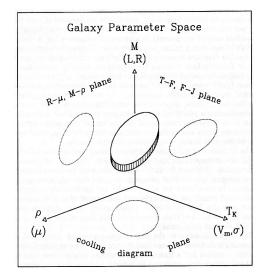

Mass based fundamental plane

FP from numerical simulations

Projections of the FP

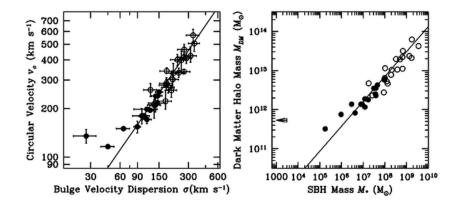

・ ・ きょう ・ きょう

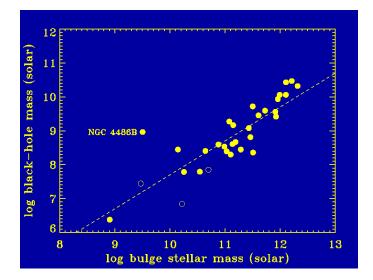

determine to within a few percent or less:

- Mass, luminosity (in any OIR band)
- Any consistently defined radius
- Surface brightness or projected mass density
- Derived 3-d luminosity, mass, or phase-space density
- Central projected radial velocity dispersion
- OIR colors, line strengths, and metallicity
- Mass of the central black hole

- Star formation and merging formative/evolutionary history
- Large-scale environment (to within a few %)
- Details of the internal structure and dynamics (including S0's)
- Projection effects (the direction we are looking from)

and most interestingly

IUCAA-NCRA Grad School 14/43

- Many of galaxy scaling relations may be driven by the properties of their dark halos
- It is possible to infer their properties from detailed dynamical profiles of galaxies and some modeling
- Numerical simulations suggest a universal form of the dark halo density profile (NFW = Navarro, Frenk & White):

$$\rho(r) = \frac{\rho_0}{(r/r_s)(1+r/r_s)^2}$$

where ρ_0 and the scale radius r_s are parameters that vary from halo to halo.

A B F A B F

He calculated the mass of the Coma cluster using the virial theorem. $M_{\rm cl} = \sigma^2 R_{\rm cl}/G$. For typical clusters $\sigma \sim 500 - 1500 \,\mathrm{km} \,\mathrm{s}^{-1}$, $R_{\rm cl} \sim 3 - 5$ Mpc. This gives $M_{\rm cl} \sim 10^{14} - 10^{15} M_{\odot}$. Typical clusters have 100-1000 galaxies and $L_{\rm cl} \sim 10^{12} L_{\odot}$ and $(M/L) \sim 200 - 500$ in solar units.

- Massive neutrinos: Known to exist and to have mass, but how much?
- Weakly Interacting Massive Particles (WIMPs): Not found yet, but possible . A generic category, e.g., the neutralino = the least massive SUSY particle; also include gravitinos, photinos, and higgsino. Possible masses > 10 GeV
- Axions: predicted in some versions of quantum chromodynamics, Could interact electromagnetically, Possible masses 10⁻¹² eV to 1 MeV
- Many (many!) other speculative possibilities ...

A B F A B F

- Hot (HDM): matter is relativistic, so must involve low-mass particles such as neutrinos. Their streaming erases the small-scale density fluctuations, so big structures form first, then later fragment. This is "top-down" structure formation
- Cold (CDM): matter moves more slowly; includes exotic as yet unknown particles such as axions, WIMPs, etc. Density fluctuations at all scales survive. Small fluctuations collapse first, then larger ones (pulling in the littler ones along the way). This is "bottom-up" structure formation and this is the best match to what we observe.
- There is probably a little bit of HDM and a lot of CDM

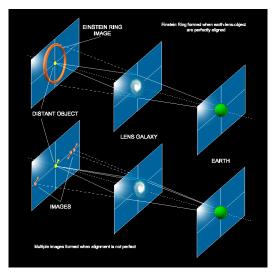

Bending of light is similar to deflection of massive particles, except that GR predicts that for photons the bending is exactly twice the Newtonian value:

$$\alpha = \frac{4GM}{bc^2} = \frac{2R_S}{b}$$

where R_s is the Schwarzschild radius of a body of mass M, and b is the impact parameter. This formula is valid if $b >> R_s$: The deflection angle α will be small e.g., for the stars near the Solar limb, \sim 2 arcsec

What does lensing tell us that photons and kinematic modeling/virial theorem doesn't?

 photons only provide information about objects that emit/absorb/reflect light - what about dark matter?

What does lensing tell us that photons and kinematic modeling/virial theorem doesn't?

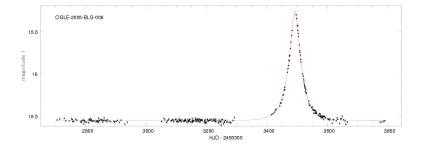

- photons only provide information about objects that emit/absorb/reflect light - what about dark matter?
- probing dark matter requires additional assumptions with lensing no need for knowledge of orbits (spiral galaxies or stars around a supermassive black hole) or of virialised state (ellipticals) to convert velocity (dispersion) measurements to mass measurements.

A B F A B F

There are ongoing searches to use lensing to find a type of dark matter called MACHOs (massive compact halo objects). Although MACHOs, as dark matter, cannot be seen themselves, if they pass in front of a source (e.g. a star nearby), they can cause the star to become brighter for a while, e.g. days or weeks. This effect has been observed but determinations of the dark matter are not yet conclusive. Microlensing observations are underway by many groups.

Microlensing in the synoptic era

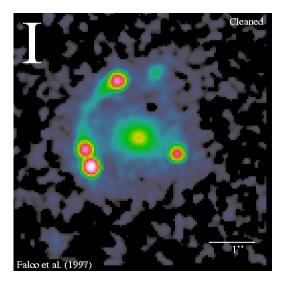

Rubin/LSST: An optical/near-IR survey of half the sky in *ugrizy* bands to $r \sim 27.5$ based on ~ 1000 visits over a 10-year period

- The main wide-fast-deep survey will use about 90% of the observing time and will be simultaneously optimized for the homogeneity of depth and number of visits, and for time- domain science (e.g., asteroids, supernovae, variable stars).
- The remaining observing time will be used to obtain improved coverage of parameter space such as very deep observations, observations with very short revisit times, and observations of "special" regions (e.g., the Ecliptic, the Large and Small Magellanic Clouds).
